## IFT 6269: Probabilistic Graphical Models

Lecturer: Simon Lacoste-Julien
Scribe: Zakaria Soliman

Disclaimer: These notes have only been lightly proofread.

### 6.1 Linear Regression

### 6.1.1 Motivation

We want to learn a prediction function $f: \mathcal{X} \rightarrow \mathcal{Y}$. Where $\mathcal{X} \subseteq \mathbb{R}^{d}$ and if:
(1) $\mathcal{Y}=\{0,1\}$, it's a binary classification
(2) $\mathcal{Y}=\{0,1, \cdots, k\}$, it's a multiclass classification
(3) $\mathcal{Y} \subseteq \mathbb{R}$, it's a regression problem.

There are several perspectives in modeling the distribution of the data:

## generative perspective

Here, we model the joint distribution $p(x, y)$. We make more assumptions in this case. This leads it to be less robust for predictions (but is a more flexible approach if we are not sure what is the task we are trying to solve).

## conditional perspective

We only model the conditional probability $p(y \mid x)$. Early 2000s, it was called the discriminative perspective, but Simon prefers to refer to it now as the conditional approach.

## fully discriminative perspective

Models $f: \mathcal{X} \rightarrow \mathcal{Y}$ directly and estimate the function $\hat{f}$ by using the loss $\ell\left(y, y^{\prime}\right)$ information. This approach is the most robust.

### 6.1.2 Linear regression model

We take a conditional approach to regression. Let $Y \in \mathbb{R}$ and let's assume that $Y$ depends linearly on $X \in R^{d}$. Linear regression is a model of the following form:

$$
p(y \mid \mathbf{x}, \mathbf{w})=\mathcal{N}\left(y \mid\langle\mathbf{w}, \mathbf{x}\rangle, \sigma^{2}\right)
$$

Where $\mathbf{w} \in \mathbb{R}^{d}$ is the parameter (or weight) vector. Equivalently, we could also rewrite the model as

$$
Y=\mathbf{w}^{\top} \mathbf{X}+\epsilon
$$

Where the noise $\epsilon \sim \mathcal{N}\left(0, \sigma^{2}\right)$ is a random variable that is independent of $X$
Remark 6.1.1 Note that if there is an offset $w_{0} \in \mathbb{R}$, that is, if $Y=w_{0}+\mathbf{w}^{\top} X+\epsilon$, we will use an "offset" notation for $\mathbf{x}$ :

$$
\mathbf{x}=\binom{\tilde{\mathbf{x}}}{1}
$$

where $\tilde{\mathbf{x}} \in \mathbb{R}^{d-1}$ and 1 is the constant feature. Thus, we have:

$$
\mathbf{w}^{\top} \mathbf{x}=\mathbf{w}_{1: d-1}^{\top} \tilde{\mathbf{x}}+w_{d}
$$

Where $w_{d}$ is the bias/offset
Let $D=\left(\mathbf{x}_{n}, y_{n}\right)_{i=1}^{n}$ be a training set of conditionally i.i.d. random variables i.e. $X_{i} \sim$ whatever and $Y_{i} \mid X_{i} \sim \mathcal{N}\left(\left\langle\mathbf{w}, X_{i}\right\rangle, \sigma^{2}\right)$. Each $y_{i}$ is a response on observation $\mathbf{x}_{i}$. We consider the conditional likelihood of all outputs given all inputs:

$$
p\left(y_{1}, \cdots, y_{n} \mid \mathbf{x}_{1}, \cdots, \mathbf{x}_{n} ; \mathbf{w}, \sigma^{2}\right)=\prod_{i=1}^{n} p\left(y_{i} \mid \mathbf{x}_{i} ; \mathbf{w}, \sigma^{2}\right) .
$$

And we have that $Y_{i} \mid X_{i} \stackrel{\text { indep }}{\sim} \mathcal{N}\left(\mathbf{w}^{\top} X_{i}, \sigma^{2}\right)$ (i.e. $\left.p\left(y_{i} \mid \mathbf{x}_{i}\right)=\frac{1}{\sqrt{2 \pi \sigma^{2}}} \exp \left(\frac{-\left(y_{i}-\mathbf{w}^{\top} \mathbf{x}_{i}\right)^{2}}{2 \sigma^{2}}\right)\right)$ taking the log-likelihood gives us the following expression:

$$
\begin{aligned}
\log p\left(y_{1: n} \mid \mathbf{x}_{1: n} ; \mathbf{w}, \sigma^{2}\right) & =\sum_{i=1}^{n} \log p\left(y_{i} \mid \mathbf{x}_{i}\right) \\
& =\sum_{i=1}^{n}\left[-\frac{\left(y_{i}-\mathbf{w}^{\top} \mathbf{x}_{i}\right)^{2}}{2 \sigma^{2}}-\frac{1}{2} \log \left(2 \pi \sigma^{2}\right)\right] \\
& =-\frac{n}{2} \log \left(2 \pi \sigma^{2}\right)-\frac{1}{2} \sum_{i=1}^{n} \frac{\left(y_{i}-\mathbf{w}^{\top} \mathbf{x}_{i}\right)^{2}}{\sigma^{2}} .
\end{aligned}
$$

Notice that maximizing the likelihood comes down to the following minimization problem w.r.t. w:

$$
\text { find } \quad \hat{\mathbf{w}}=\arg \min _{\mathbf{w}} \sum_{i=1}^{n}\left(y_{i}-\mathbf{w}^{\top} \mathbf{x}_{i}\right)^{2} .
$$

Define the design matrix $\mathbf{X}$ as

$$
\mathbf{X}=\left(\begin{array}{c}
-\mathbf{x}_{1}^{\top}- \\
\vdots \\
-\mathbf{x}_{n}^{\top}
\end{array}\right) \in \mathbb{R}^{n \times d}
$$

and denote by $\mathbf{y}$ the vector of coordinates $\left(\begin{array}{c}y_{1} \\ \vdots \\ y_{n}\end{array}\right)$. This notation allows us to rewrite the residual sum of squares in a more compact fashion as:

$$
\sum_{i=1}^{n}\left(y_{i}-\mathbf{w}^{\top} \mathbf{x}_{i}\right)^{2}=\|\mathbf{y}-\mathbf{X} \mathbf{w}\|^{2}
$$

Thus, we can rewrite the log likelihood as:

$$
-\log p(\mathbf{y} \mid \mathbf{x})=\frac{\|\mathbf{y}-\mathbf{X} \mathbf{w}\|^{2}}{2 \sigma^{2}}+\frac{n}{2} \log \left(2 \pi \sigma^{2}\right)
$$

Finally, the minimization problem over $\mathbf{w}$ can be rewritten as:

$$
\text { find } \quad \hat{\mathbf{w}}=\arg \min _{\mathbf{w}}\|\mathbf{y}-\mathbf{X} \mathbf{w}\|^{2}
$$

Remark 6.1.2 The minimization of $\|\mathbf{y}-\mathbf{X} \mathbf{w}\|^{2}$ w.r.t. $\mathbf{w}$ can also be viewed geometrically as choosing $\hat{\mathbf{w}}$ so that the vector $\mathbf{X} \hat{\mathbf{w}}$ is the orthogonal projection of $\mathbf{y}$ onto the column space of $\mathbf{X}$

Now let us find $\hat{\mathbf{w}}$ :

$$
\begin{array}{rlr}
\frac{\partial}{\partial \mathbf{w}}(\mathbf{y}-\mathbf{X} \mathbf{w})^{\top}(\mathbf{y}-\mathbf{X} \mathbf{w}) & =\frac{\partial}{\partial \mathbf{w}}\left[\|\mathbf{y}\|^{2}-2 \mathbf{y}^{\top} \mathbf{X} \mathbf{w}+\mathbf{w}^{\top} \mathbf{X}^{\top} \mathbf{X} \mathbf{w}\right] & \\
& \left.=0-2 \mathbf{X}^{\top} \mathbf{y}+2 \mathbf{X}^{\top} \mathbf{X} \mathbf{w}=0 \quad\left(\text { using } \nabla_{\mathbf{w}}\left(\mathbf{w}^{\top} \mathbf{A w}\right)=\left(\mathbf{A}+\mathbf{A}^{\top}\right) \mathbf{w}\right)\right) \\
& \Longleftrightarrow\left(\mathbf{X}^{\top} \mathbf{X}\right) \mathbf{w}=\mathbf{X}^{\top} \mathbf{y} &
\end{array}
$$

- If $\mathbf{X}^{\top} \mathbf{X}$ is invertible, there is a unique solution $\hat{\mathbf{w}}=\left(\mathbf{X}^{\top} \mathbf{X}\right)^{-1} \mathbf{X}^{\top} \mathbf{y}$
- If $n<d$, then $\mathbf{X}$ is not full rank and so $\mathbf{X}^{\top} \mathbf{X}$ is not invertible. In this case we could use the pseudo-inverse of $\mathbf{X}, \mathbf{X}^{\dagger}$ and choose the minimum norm $\|\mathbf{w}\|$ solution amongst $\arg \min _{\mathbf{w}}\|\mathbf{y}-\mathbf{X w}\|^{2}$. The problem we face is that the pseudo-inverse is not numerically stable.

In the latter case, it would be better to use regularization techniques (see next section).

### 6.1.3 Ridge regression

We can either interpret ridge regression as adding a norm regularizer to the least-square EMR, or as replacing the MLE for $\mathbf{w}$ with a MAP by adding a prior $p(\mathbf{w})$ :

$$
\log p(\mathbf{w} \mid \mathbf{y}, \mathbf{x})=\log p\left(y_{1: n} \mid \mathbf{x}_{1: n} ; \mathbf{w}\right)+\log p(\mathbf{w})+c s t
$$

Where $p(\mathbf{w})$ is the prior over $\mathbf{w}$ and:

$$
p(\mathbf{w})=\mathcal{N}\left(\mathbf{w} \mid 0, \frac{\mathbf{I}}{\lambda}\right)
$$

So we have that:

$$
\log p(\mathbf{w} \mid \mathbf{y}, \mathbf{x})=\log p\left(y_{1: n} \mid \mathbf{x}_{1: n} ; \mathbf{w}\right)+c s t-\frac{\lambda}{2}\|\mathbf{w}\|^{2}
$$

and then,

$$
\begin{aligned}
\nabla_{\mathbf{w}}=0 & \Rightarrow\left(\mathbf{X}^{\top} \mathbf{X}+\lambda \mathbf{I}\right) \mathbf{w}=\mathbf{X}^{\top} \mathbf{y} \\
& \Rightarrow \hat{\mathbf{w}}_{M A P}=\left(\mathbf{X}^{\top} \mathbf{X}+\lambda \mathbf{I}\right)^{-1} \mathbf{X}^{\top} \mathbf{y}
\end{aligned}
$$

Notice that $\left(\mathbf{X}^{\top} \mathbf{X}+\lambda \mathbf{I}\right)$ is always invertible.
Remark 6.1.3 $-\log p(\mathbf{w} \mid \mathbf{y}, \mathbf{x})$ is strongly convex in $\mathbf{w}$. So there is a unique global minimum

Remark 6.1.4 It is good practice to standardize or normalize the features. Standardizing means make the features have empirical zero mean and unit standard deviation; normalizing can mean different things, e.g. scale them to $[0,1]$ or to a unit norm.

### 6.2 Logistic Regression

Let's turn our attention to classification problems. For this model, we will assume that $Y \in\{0,1\}$ and $X \in \mathbb{R}^{d}$. We make no additional assumptions apart that $p(\mathbf{x} \mid Y=1)$ and $p(\mathbf{x} \mid Y=0)$ are densities. Our goal is to model $p(Y \mid X)$

$$
\begin{aligned}
p(Y=1 \mid X=\mathbf{x}) & =\frac{p(Y=1, X=\mathbf{x})}{p(Y=1, X=\mathbf{x})+p(Y=0, X=\mathbf{x})} \\
& =\frac{1}{1+\frac{p(Y=1, X=\mathbf{x})}{p(Y=0, X=\mathbf{x})}} \\
& =\frac{1}{1+\exp (-f(\mathbf{x}))}
\end{aligned}
$$

Figure 6.1: Sigmoid function.

Where

$$
f(x)=\log \underbrace{\frac{p(X=\mathbf{x} \mid Y=1)}{p(X=\mathbf{x} \mid Y=0)}}_{\text {class-conditional ratio }}+\log \underbrace{\frac{p(Y=1)}{p(Y=0)}}_{\text {prior odd ratio }}
$$

Is the $\log$ odds ratio. In general we have:

$$
p(Y=1 \mid X=\mathbf{x})=\sigma(f(\mathbf{x}))
$$

where $\sigma(z):=\frac{1}{1+e^{-z}}$ is the sigmoid function shown in Figure 2.1.

The sigmoid function has the following properties:

## Property 6.2.1

$$
\forall z \in \mathbb{R}, \sigma(-z)=1-\sigma(z)
$$

## Property 6.2.2

$$
\forall z \in \mathbb{R}, \sigma^{\prime}(z)=\sigma(z)(1-\sigma(z))=\sigma(z) \sigma(-z)
$$

Example 6.2.1 Finally, we make the following observation that a very large class of probabilistic models yield logistic-regression types of models (thus explaining why logistic regression is fairly robust).

Consider that the class conditional is in the exponential family:

$$
\begin{gathered}
p(\mathbf{x} \mid \boldsymbol{\eta})=h(\mathbf{x}) \exp \left(\boldsymbol{\eta}^{\top} \mathbf{T}(\mathbf{x})-A(\boldsymbol{\eta})\right) . \\
f(\mathbf{x})=\log \frac{p(X=\mathbf{x} \mid Y=1)}{p(X=\mathbf{x} \mid Y=0)}+\log \frac{p(Y=1)}{p(Y=0)} \\
=\left(\boldsymbol{\eta}_{1}-\boldsymbol{\eta}_{0}\right)^{\top} \mathbf{T}(\mathbf{x})+A\left(\boldsymbol{\eta}_{0}\right)-A\left(\boldsymbol{\eta}_{1}\right)+\log \left(\frac{\pi}{1-\pi}\right) \\
=\mathbf{w}^{\top} \boldsymbol{\phi}(\mathbf{x})
\end{gathered}
$$

Where $\mathbf{w}=\binom{\eta_{1}-\eta_{0}}{A\left(\boldsymbol{\eta}_{0}\right)-A\left(\boldsymbol{\eta}_{1}\right)+\log \left(\frac{\pi}{1-\pi}\right)}$ and $\boldsymbol{\phi}(\mathbf{x})=\binom{\mathbf{T}(\mathbf{x})}{1}$. Thus we have a logistic regression model with features $\boldsymbol{\phi}(\mathbf{x})$ :

$$
p(y=1 \mid \mathbf{x})=\sigma\left(\mathbf{w}^{\top} \boldsymbol{\phi}(\mathbf{x})\right)
$$
