## Abstract

The lattice structure of conventional linear congruential random number generators (LCGs), over integers, is well known. In this paper, we study LCGs in the field of formal Laurent series, with coefficient in the Galois field  $\mathbb{F}_2$ . The state of the generator (a Laurent series) evolves according to a linear recursion and can be mapped to a number between 0 and 1, producing what we call a LS2 sequence. In particular, the sequences produced by simple or combined Tausworthe generators are special cases of LS2 sequences. By analyzing the lattice structure of the LCG, we obtain a precise description of how all the  $k$ -dimensional vectors formed by successive values in the LS2 sequence are distributed in the unit hypercube. More specifically, for any partition of the  $k$ -dimensional hypercube into  $2^{kl}$  identical subcubes, we can quickly compute a table giving the exact number of subcubes that contain exactly  $n$  points, for each integer  $n$ . We give many examples which illustrate the practical implications of our results.

## Résumé

La structure de réseau des générateurs à congruence linéaire (GCL) ordinaires, définis sur les entiers, est bien connue. Dans cet article, nous étudions les GCL dans le corps des séries formelles de Laurent, avec coefficients dans le corps de Galois  $\mathbb{F}_2$ . L'état du générateur (une série de Laurent) évolue selon une récurrence linéaire. On définit une application faisant correspondre à chaque série de Laurent un nombre réel entre 0 et 1 et la suite de ces valeurs, produites par le générateur, forme ce que l'on appelle une suite LS2. Les suites produites par des générateurs de type Tausworthe simples ou combinés sont en fait des cas particuliers de suites LS2. En analysant la structure de réseau d'un tel générateur, on obtient une description précise de la façon dont tous les vecteurs de dimension  $k$ , dont les composantes sont des valeurs successives de la suite, sont distribués dans l'hypercube unitaire  $[0, 1]^k$ . Plus précisément, pour chaque partition de cet hypercube en  $2^{kl}$  sous-cubes de même taille, nous pouvons calculer rapidement combien de sous-cubes contiennent exactement  $n$  points, pour chaque entier  $n$ . Nos résultats théoriques sont illustrés par plusieurs exemples numériques.

# 1. INTRODUCTION

Following Tezuka [12, 13], we consider the analogue of a multiplicative linear congruential generator in the field  $K$  of formal Laurent expansions (at infinity) with coefficients in the Galois field  $\mathbb{F}_2$ :

$$x = \alpha_n z^n + \alpha_{n-1} z^{n-1} + \dots \tag{1}$$

where  $n$  is any integer. This generator is conveniently defined with the help of the operators:

$$\begin{aligned} \text{frac}(x) &= \alpha_{-1} z^{-1} + \alpha_{-2} z^{-2} + \dots, \\ \text{trunc}_l(x) &= \alpha_n z^n + \alpha_{n-1} z^{n-1} + \dots + \alpha_{-l} z^{-l} \end{aligned}$$

for  $x \in K$  defined as in (1) and  $l \in \mathbb{Z}$ . Let  $a$  (the *multiplier*) and  $m$  (the *modulus*) be non-zero elements in  $K$ . For  $l > 0$ , we consider the pseudorandom sequence:

$$u_i = \text{trunc}_l(\text{frac}(a^i/m)), \quad i = 0, 1, 2, \dots \tag{2}$$

One can identify any element  $x$  expressed as in (1) with the real number  $\alpha_n 2^n + \alpha_{n-1} 2^{n-1} + \dots$ , where each  $\alpha_i \in \mathbb{F}_2$  is identified with its representative integer 0 or 1. The sequence (2) in  $K$  is then identified with a pseudorandom sequence in the interval  $[0, 1)$ , which we call a LS2 (Laurent Series over  $\mathbb{F}_2$ ) sequence. As pointed out by Tezuka [12, 13], the usual Tausworthe sequences, as well as their combinations by means of addition modulo two, are instances of this scheme. Tezuka has also shown the influence of the last and first successive minima of certain lattices in  $K^k$  associated with combined generators, and with their components, on their  $k$ -distribution properties.

The aim of this paper is to show that a more complete description of the  $k$ -distribution involves all successive minima for the corresponding lattices. For any partition of the  $k$ -dimensional hypercube into  $2^{kl}$  identical subcubes, we show how to quickly compute a table giving the number of subcubes that contain exactly  $n$  points, for each integer  $n$ .

In Section 2, we recall some facts concerning lattices in a field of series and prove a key theorem from which the rest of our results will follow. Section 3 gives a precise statement of the  $k$ -distribution problem that we want to address. We solve that problem in Section 4 for the case of a prime modulus  $m$  and in Section 5 for the case of combined generators with two or three components. In all cases, we assume (among other things) that  $a$  and  $m$  are polynomials in  $K$  and that the generator has (full) period  $2^p - 1$ , where  $p$  is the degree of  $m$ . In Section 6, we give numerical examples illustrating the practical implications of our results.

## 2. LATTICES

Following Mahler [6], we define a non-Archimedean valuation in  $K$  by

$$|x| = \begin{cases} 0 & \text{if } x = 0; \\ 2^n & \text{if } x \neq 0 \text{ and } x \text{ is given by (1) with } \alpha_n \neq 0. \end{cases}$$

This makes  $K$  a locally compact field. Let  $k$  denote a positive integer. The vector space  $K^k$  is then normed by  $\|X\| = \max_{1 \leq i \leq k} |x_i|$ , where  $X = (x_1, \dots, x_k)$ , and it is also locally compact.

We now consider, in  $K$ , the subring of polynomials  $A = \mathbb{F}_2[z]$  and  $A$ -submodules of  $K^k$ . We call one such submodule a *lattice* if it is discrete in  $K^k$ . We will not assume, as is usually done, that a lattice has maximal rank over  $A$ . One may then define its rank as the dimension of the  $K$ -vector subspace it generates. We note that, because of local compactness, linear independence in a lattice is the same over  $A$  as over  $K$ . We will make use of the following result (see the proof of lemma 1 of [7]).

**THEOREM 1.** *Let  $X_1, \dots, X_h$  be points in a lattice  $L \subset K^k$  of rank  $h$  with the following properties:*

- (i)  $X_1$  is a shortest non-zero vector in  $L$ ;
- (ii) for  $i = 2, \dots, h$ ,  $X_i$  is a shortest vector among the set of vectors  $X$  in  $L$  such that  $X_1, \dots, X_{i-1}, X$  are linearly independent over  $A$ .

Then,  $X_1, \dots, X_h$  form a basis of  $L$  over  $A$ . ■

Since any cube  $C_r = \{X \mid \|X\| < 2^r\}$ ,  $r \in \mathbb{Z}$ , contains but a finite number of points in a given lattice  $L$ , it follows that a system as in Theorem 1 always exists. This system is a *reduced* basis for  $L$  (in the sense of Minkowski). The numbers  $\sigma_i = \|X_i\| > 0$  are then uniquely determined by the lattice and are called its *successive minima*. Lenstra [4] gives details on how to compute these numbers (and a reduced basis) efficiently when the lattice is integral (i.e., contained in  $A^k$ ).

One can view  $L \cap C_r$  as a vector space over  $\mathbb{F}_2$ , with cardinality  $2^d$ , where  $d$  is its finite dimension over  $\mathbb{F}_2$ . In the next Theorem, we show that the number  $2^d$  of lattice points in the cube  $C_r$  is determined by  $r$  and the lattice's successive minima. Let  $s_i = \log_2 \sigma_i$  (an integer). For  $t \in \mathbb{R}$ , let  $t^+$  denote  $\max(t, 0)$ .

**THEOREM 2.** *One has:*

$$d = \sum_{i=1}^h (r - s_i)^+. \quad (3)$$

PROOF. Let  $X_1, \dots, X_h$  be as in Theorem 1. For each integer  $j \geq 0$ , let  $h_j = \max\{i \leq h \mid s_i \leq j\}$  be the number of points  $X_i$  contained in  $C_{j+1}$  and, for  $1 \leq i \leq h_j$ , let  $X_i^{(j)} = z^{j-s_i} X_i$ . Then,  $\|X_i^{(j)}\| = 2^j$ . We will now prove that the system  $\mathcal{B} = \{X_i^{(j)} \mid j < r, 1 \leq i \leq h_j\}$  is a basis for  $L \cap C_r$  over  $\mathbb{F}_2$ . From that, equation (3) easily follows.

We show first that for each  $j \geq s_1$ , the system  $X_1^{(j)}, \dots, X_{h_j}^{(j)}$  is linearly independent over  $\mathbb{F}_2$  modulo  $C_j$ . Let us prove that property by induction on  $j$ . For  $j = s_1$ , one has  $h_j = \max\{i \leq h \mid s_i = s_1 = j\}$  and the vectors  $X_1^{(j)}, \dots, X_{h_j}^{(j)}$  are in fact  $X_1, \dots, X_{h_j}$ , which are linearly independent by construction. Now, let  $j \geq s_1 + 1$  and assume that  $X_1^{(j-1)}, \dots, X_{h_{j-1}}^{(j-1)}$  are linearly independent over  $\mathbb{F}_2$  modulo  $C_{j-1}$ . Let  $X \in C_j$  be a linear combination over  $\mathbb{F}_2$  of  $X_1^{(j)}, \dots, X_{h_j}^{(j)}$ . If  $j = s_i$  for some  $i$ , let  $l = \min\{i \mid s_i = j\}$ . This linear combination cannot involve any of  $X_l^{(j)}, \dots, X_{h_j}^{(j)}$  (that is,  $X_l, \dots, X_{h_j}$ ), since  $X$  would be linearly independent of  $X_1, \dots, X_{l-1}$  (and shorter than  $X_l$ ) contradicting the minimality property of  $X_l$ . If  $j \neq s_i$  for all  $i$ , then  $h_j = h_{j-1}$ . Therefore, in both cases, the linear combination can involve only  $X_1^{(j)}, \dots, X_{h_{j-1}}^{(j)}$ . For these we have  $X_i^{(j)} = z X_i^{(j-1)}$  and, since multiplication by  $z$  is a linear (over  $\mathbb{F}_2$ ) automorphism of  $K^k$  mapping  $C_{j-1}$  onto  $C_j$ , it follows that they are linearly independent over  $\mathbb{F}_2$  modulo  $C_j$  and our linear combination must be trivial. This completes the induction.

We are now ready to show that  $\mathcal{B}$  is a basis, i.e. that it is linearly independent and that every vector of  $L \cap C_r$  can be expressed as a linear combination of vectors of  $\mathcal{B}$ . Let  $X \in L$ . From Theorem 1,  $X$  can be expressed uniquely as a linear combination of  $X_1, \dots, X_h$ , with coefficients in  $A$ , that is

$$X = \sum_{i=1}^h \sum_{n \geq 0} c_{in} z^n X_i = \sum_{i=1}^h \sum_{j \geq s_i} \tilde{c}_{ij} X_i^{(j)}, \quad (4)$$

where each  $c_{in} = \tilde{c}_{i, s_i+n}$  is in  $\mathbb{F}_2$  and there are finitely many non-zero  $c_{in}$ 's. Since the  $c_{in}$ 's are unique, the  $\tilde{c}_{in}$ 's are also unique. If  $X = 0$ , then each  $c_{in}$  must be zero because the  $X_i$ 's are independent over  $A$ . As a consequence, if  $X = 0$ , each  $\tilde{c}_{ij}$  must be zero, which implies that  $\mathcal{B}$  is linearly independent over  $\mathbb{F}_2$ .

It remains to show that, if  $X \in C_r$ ,  $\tilde{c}_{ij} \neq 0$  implies  $j < r$ . Let  $l = \max\{j \mid \tilde{c}_{ij} \neq 0\}$ . One has  $l \geq s_1$ , because  $s_1 \leq s_2 \leq \dots \leq s_k$  and the sum in (4) is for  $j \geq s_i$ . Suppose that  $l \geq r$  and let

$$\tilde{X} = \sum_{i=1}^h \tilde{c}_{il} X_i^{(l)} = X - \sum_{i=1}^h \sum_{j=s_i}^{l-1} \tilde{c}_{ij} X_i^{(j)}.$$

Since  $X \in C_r \subseteq C_l$  and  $X_i^{(j)} \in C_l$  for each  $j < l$ , one has  $\tilde{X} \in C_l$ . In other words,  $\tilde{X} = 0$  modulo  $C_l$ . Since  $X_1^{(l)}, \dots, X_{h_l}^{(l)}$  are linearly independent modulo  $C_l$ , this implies  $\tilde{c}_{il} = 0$  for each  $i$ , which contradicts the definition of  $l$ . Therefore,  $l < r$  and the conclusion follows. ■

### 3. THE QUESTION OF $k$ -DISTRIBUTION

For the remainder of the paper, we assume given  $a, m \in K$  satisfying the following assumptions:

- (A1)  $a, m \in A$ ;
- (A2) The group  $(A/(m))^\times$  of invertible elements of the quotient ring  $A/(m)$  is cyclic and  $a$  is a generator for it;
- (A3)  $m$  has no factor of the first degree. ■

We consider all  $k$ -tuples of successive non-truncated terms of (2):

$$R_i = (\text{frac}(a^i/m), \dots, \text{frac}(a^{i+k-1}/m)), \quad i = 0, 1, \dots$$

and the  $A$ -submodule of  $K^k$  defined by

$$L = AR_0 + A^k.$$

From A1,  $L$  is a lattice that contains all the  $R_i$ 's. We call it the lattice *associated* with the pseudorandom sequence defined by  $a$  and  $m$ . The mapping  $x \rightarrow \text{frac}(xR_0)$ ,  $x \in A$ , where  $\text{frac}$  is applied componentwise, induces an isomorphism

$$A/(m) \simeq L \cap C_0 \tag{5}$$

and, if  $S$  is the subset of  $L \cap C_0$  that corresponds to  $(A/(m))^\times$ , it follows from A2 that the sequence  $\{R_i, i = 0, 1, \dots\}$  runs cyclically through all points of  $S$  and that each point is visited exactly once per period.

For each integer  $l \geq 0$ , let  $E_l = \text{trunc}_l(C_0)$ , where  $\text{trunc}_l$  is applied componentwise. The operator  $\text{trunc}_l$  then defines a linear transformation over  $\mathbb{F}_2$ ,

$$\text{trunc}_l : L \cap C_0 \rightarrow E_l. \tag{6}$$

We now define a frequency function  $f_l : E_l \rightarrow \mathbb{N} \cup \{0\}$  by

$$f_l(X) = \text{card}\{R \in S \mid \text{trunc}_l(R) = X\}.$$

The set  $E_l$  corresponds to a partition of the hypercube  $[0, 1]^k$  into  $2^{lk}$  cubic cells of the same size; we note that, if  $X \in E_l$  and  $R \in S$ , the condition  $\text{trunc}_l(R) = X$  means that the point in  $\mathbb{R}^k$  corresponding to  $R$  lies (strictly, because of A3) inside the cube  $\prod_{i=1}^k [x_i, x_i + 2^{-l})$  where  $x_i$  is the real number corresponding to the  $i$ -th coordinate of  $X$ ;  $f_l(X)$  is then the number of such points  $R \in S$  falling into this cube. For each integer  $n$ , let

$$\varphi_l(n) = \text{card}\{X \in E_l \mid f_l(X) = n\},$$

which represents the number of cells that contain exactly  $n$  points. We will be concerned in the next sections with the problem of computing  $\varphi_l(n)$  efficiently for every non-negative integer  $n$ .

#### 4. SIMPLE GENERATORS

We first consider the case where the polynomial  $m$  is irreducible. Let  $p$  be the degree of  $m$ . From (5) we see that  $S = L \cap C_0 \setminus \{0\}$ . Also, the kernel of the mapping (6) is  $L \cap C_{-l}$  and, if we denote its image by  $L^{(l)}$ , we obtain for  $X \in E_l$ ,

$$f_l(X) = \begin{cases} 0 & \text{if } X \in E_l \setminus L^{(l)}; \\ \text{card}(L \cap C_{-l}) & \text{if } X \in L^{(l)} \setminus \{0\}; \\ \text{card}(L \cap C_{-l}) - 1 & \text{if } X = 0. \end{cases}$$

Now,  $\text{card}(L \cap C_{-l}) = 2^d$ , where  $d$  is given in Theorem 2 with  $r = -l$  and  $h = k$ . Then, from (6) and (5),  $\dim_{\mathbb{F}_2}(L^{(l)}) = \dim_{\mathbb{F}_2}(L \cap C_0) - d = p - d$ . Since  $\dim_{\mathbb{F}_2}(E_l) = kl$ , there are  $2^{kl} - 2^{p-d}$  points in  $E_l \setminus L^{(l)}$  and  $2^{p-d}$  points in  $L^{(l)}$ . This is summarized in Table 1, which gives the value of  $\varphi_l(n)$  for all values of  $n$  for which it could be non-zero.

Table 1: Values of  $\varphi_l(n)$  that could be non-zero.

$n$	$\varphi_l(n)$
$2^d$	$2^{p-d} - 1$
$2^d - 1$	1
0	$2^{lk} - 2^{p-d}$

Tezuka [12] calls the pseudorandom sequence  $k$ -distributed with resolution  $l$  when the case  $n = 0$  does not occur, i.e. when

$$lk = p - d. \tag{7}$$

In the trivial case  $l = 0$ , we have  $E_l = \{0\}$  and  $d = p$  so that (7) holds. As  $l$  increases through successive integers,  $r = -l$  correspondingly decreases and by Theorem 2, (7) remains valid if and only if  $r \geq \log \sigma_k$  (note that  $\log \sigma_k \leq 0$  since  $A^k \subset L$ ). This gives another proof of the following result of Tezuka [12, Theorem 1]:

**COROLLARY 1.** *A simple pseudo-random sequence in  $K$  defined by  $a$  and  $m$  is  $k$ -distributed with resolution  $l$  if and only if  $\log \sigma_k \leq -l$ . ■*

## 5. COMBINED GENERATORS WITH $J$ SIMPLE COMPONENTS

### 5.1. General formulæ

We consider now the case where  $m$  is a product of  $J$  prime factors,  $m = m_1 \cdots m_J$ , where for each  $j$ ,  $p_j \geq 2$  is the degree of  $m_j$  and  $p = p_1 + \cdots + p_J$  is the degree of  $m$ . Assumptions A1–A3 then hold, provided that for each pair  $i \neq j$ ,  $\text{GCD}(2^{p_i} - 1, 2^{p_j} - 1) = 1$ . For  $j = 1, \dots, J$ , let  $L_j$  be the lattice in  $K^k$  associated with the LS2 sequence defined by  $(a, m_j)$ .

By the Chinese Remainder theorem, we have a ring isomorphism

$$A/(m_1) \times \cdots \times A/(m_J) \simeq A/(m). \quad (8)$$

Through (5), this becomes

$$L \cap C_0 = (L_1 \cap C_0) \oplus \cdots \oplus (L_J \cap C_0) \quad (9)$$

(direct sum of vector spaces over  $\mathbb{F}_2$ ). For each  $j$ , define  $V_j = L_j \cap C_0$ . For each subset  $\Psi$  of  $\{1, \dots, J\}$ , define  $m_\Psi = \prod_{j \in \Psi} m_j$ ,  $V_\Psi = \bigoplus_{j \in \Psi} V_j$ ,  $W_\Psi = V_\Psi \cap C_{-l}$ , and  $d_\Psi = \dim(W_\Psi)$ . If  $\Psi = \{1, \dots, J\}$ , we also write  $V_\Psi$  and  $W_\Psi$  as  $V$  and  $W$  respectively. (Note that all objects and quantities defined above depend implicitly on  $k$  and  $l$ .) Each  $d_\Psi$  can be computed using (3) in Theorem 2, with  $r = -l$ ,  $h = k$ , and  $L = L_\Psi$ , where  $L_\Psi$  is the lattice associated with the LS2 sequence defined by  $(a, m_\Psi)$ . Then,

$$S = V \setminus \bigcup_{|\Psi|=J-1} V_\Psi. \quad (10)$$

For each  $X \in E_l \setminus L^{(l)}$ , one has  $f_l(X) = 0$ . Those  $X \in L^{(l)}$  correspond by (6) to the cosets  $W'$  of  $W$  in  $V$ . For any given coset  $W'$ , we define the *signature* of  $W'$  (also the signature of  $X$ ) as the set  $\Phi(W') = \{\Psi \subseteq \{1, \dots, J\} \mid W' \cap V_\Psi \neq \emptyset\}$ . Observe that for each  $W'$ ,  $\text{card}(W') = \text{card}(W) = 2^d$  and when  $W'$  intersects  $V_\Psi$ ,  $\text{card}(W' \cap V_\Psi) = \text{card}(W \cap V_\Psi) = \text{card}(W_\Psi) = 2^{d_\Psi}$ . A non-empty family  $\Phi$  of subsets of  $\{1, \dots, J\}$  such that  $\Psi \in \Phi$  and  $\Psi \subset \Psi'$  imply  $\Psi' \in \Phi$ , will be called a *maximal family*. Reciprocally, a non-empty family  $\Gamma$  of subsets of  $\{1, \dots, J\}$ , such that  $\Psi_1, \Psi_2 \in \Gamma$  implies  $\Psi_1 \not\subset \Psi_2$  and  $\Psi_2 \not\subset \Psi_1$ , will be called a *minimal family*. Let  $\Omega$  and  $\Delta$  denote the classes of all maximal and minimal families, respectively. A set  $\Psi$  belonging to a maximal family  $\Phi$  is called a *minimal element* of  $\Phi$  if no proper subset of  $\Psi$  belongs to  $\Phi$ . The set of minimal elements of  $\Phi$  will be called the *generator* of  $\Phi$ , and denoted by  $\tau(\Phi)$ . Since  $\tau(\Phi)$  contains only minimal elements, it is clearly a minimal family, that is,  $\tau(\Phi) \in \Delta$ . The next lemma shows that the mapping  $\tau : \Omega \rightarrow \Delta$  is one-to-one and onto, and also that  $\Omega$  contains all signatures.

**LEMMA 1.** *If  $\Phi$  is a signature, then  $\Phi \in \Omega$ . Also,  $\tau : \Omega \rightarrow \Delta$  is one-to-one and onto.*

PROOF. Let  $\Phi = \Phi(W')$  be a signature and assume  $\Psi \in \Phi$ . Then  $W' \cap V_\Psi \neq \phi$  and, if  $\Psi \subset \Psi'$ ,  $V_\Psi$  is a subset of  $V_{\Psi'}$  and  $W' \cap V_{\Psi'} \neq \phi$ . Therefore  $\Phi \in \Omega$ . Now, let  $\Gamma \in \Delta$  and let  $\Phi$  be the family of all subsets of  $\{1, \dots, J\}$  that contain (or are equal to) some element of  $\Gamma$ . Then,  $\Phi \in \Omega$  and  $\tau(\Phi) = \Gamma$ , which proves that  $\tau$  is onto. If  $\Phi_1$  is another maximal family with  $\tau(\Phi_1) = \Gamma$ , then  $\Phi \subseteq \Phi_1$ , because  $\Gamma \subseteq \Phi_1$ , so that by the definition of  $\Phi$  and since  $\Phi_1 \in \Omega$ , every set of  $\Phi$  must be in  $\Phi_1$ . Also, since  $\tau(\Phi_1) = \Gamma$ , all sets of  $\Phi_1 \setminus \Gamma$  have proper subsets in  $\Gamma$ , which implies that  $\Phi_1 \subseteq \Phi$ . Therefore, one must have  $\Phi_1 = \Phi$ , which means that  $\tau$  is one-to-one. ■

Let  $X \in L^{(j)}$  and let  $W'$  be the coset that is mapped to  $X$ . We then have, from (10) and using a standard inclusion-exclusion argument,

$$\begin{aligned} f_i(X) &= \text{card}(W' \cap S) \\ &= \sum_{i=0}^J (-1)^i \sum_{|\Psi|=J-i} \text{card}(W' \cap V_\Psi) \\ &= \sum_{\Psi \in \Phi(W')} (-1)^{J-|\Psi|} 2^{d_\Psi}. \end{aligned} \quad (11)$$

For each  $\Phi \in \Omega$ , let  $c_\Phi$  denote the number of cosets of  $W$  (in  $V$ ) with signature  $\Phi$ . In view of (11), it will be sufficient to determine these numbers. We will use intermediate quantities

$$C_\Gamma = \text{card} \left( \left( \bigcap_{\Psi \in \Gamma} (V_\Psi + W) \right) / W \right), \quad \Gamma \in \Delta. \quad (12)$$

The quantity  $C_\Gamma$  is the number of cosets  $W'$  with signature  $\Phi = \tau^{-1}(\Gamma)$ , that is, such that  $W' \cap V_\Psi \neq \phi$  if and only if  $\Psi \in \Phi$ . They are related to the  $c_\Phi$ 's by the equations

$$\sum_{\{\Phi | \Gamma \subseteq \Phi\}} c_\Phi = C_\Gamma, \quad \Gamma \in \Delta. \quad (13)$$

Observe that the sum in (13) is over all maximal families  $\Psi$  that contains  $\tau^{-1}(\Gamma)$ . The quantities  $C_\Gamma$  will be determined, partly by Theorem 3, and completely in cases  $J = 2$  or  $3$ . In such cases, one can also compute the  $c_\Phi$ 's using (13) because of the following lemma.

**LEMMA 2.** *The linear system (13) admits a unique solution  $c_\Phi$ ,  $\Phi \in \Omega$ , for any given set of values for the  $C_\Gamma$ 's.*

PROOF. Since  $\Omega$  and  $\Delta$  have the same cardinality by lemma 1, it is sufficient to show that all  $c_\Phi$ 's are 0 if all  $C_\Gamma$ 's are 0. Suppose  $C_\Gamma = 0$  for each  $\Gamma \in \Delta$ . For each maximal family  $\Phi$ , let  $s_\Phi$  denote the number of maximal families that contain  $\Phi$ . We proceed by induction on  $s_\Phi$ . If  $s_\Phi = 1$  then, for  $\Gamma = \tau(\Phi)$ , the sum in (13) has only one term, namely  $c_\Phi$ , which must be zero. Now, let  $s > 1$  and assume that  $c_\Phi = 0$  whenever  $s_\Phi < s$ . Let  $\Phi$  be a maximal family such that  $s_\Phi = s$ . For any maximal family  $\Phi'$  that contains  $\Phi$  strictly, one must have  $s_{\Phi'} < s_\Phi = s$ , and therefore  $c_{\Phi'} = 0$ . Then,  $c_\Phi$  is the only possible non-zero term

that remains in the sum in (13) for  $\Gamma = \tau(\Phi)$ . Since that sum is zero,  $c_\Phi$  must be zero. This completes the induction. ■

For each  $\Gamma \in \Delta$ , we define

$$\gamma(\Gamma) = \dim \left( \bigcap_{\Psi \in \Gamma} (V_\Psi + W) \right) - \dim(W), \quad (14)$$

so that

$$C_\Gamma = 2^{\gamma(\Gamma)}. \quad (15)$$

**THEOREM 3.** *Let  $\Gamma \in \Delta$  and  $\Psi_0 = \bigcup_{\Psi \in \Gamma} \Psi$ . If the canonical mapping*

$$V_{\Psi_0} \rightarrow \prod_{\Psi \in \Gamma} (V_{\Psi_0}/(V_\Psi + W_{\Psi_0})) \quad (16)$$

is onto, then

$$\gamma(\Gamma) = (p_{\Psi_0} - d_{\Psi_0})(1 - |\Gamma|) + \sum_{\Psi \in \Gamma} (p_\Psi - d_\Psi). \quad (17)$$

This will be the case if  $|\Gamma| = 1$  or  $2$ . If the mapping is not onto, “=” must be replaced by “ $\geq$ ” in (17).

PROOF. The canonical mapping (16) has kernel  $\bigcap_{\Psi \in \Gamma} (V_\Psi + W_{\Psi_0})$ . But the dimension of  $V_{\Psi_0}$  must be equal to the dimension of the kernel plus the dimension of the image. That is, if the mapping is onto,

$$p_{\Psi_0} = \dim(V_{\Psi_0}) = \dim \left( \bigcap_{\Psi \in \Gamma} (V_\Psi + W_{\Psi_0}) \right) + \sum_{\Psi \in \Gamma} \dim(V_{\Psi_0}/(V_\Psi + W_{\Psi_0})).$$

Observe that  $\dim(V_{\Psi_0}/(V_\Psi + W_{\Psi_0})) = \dim(V_{\Psi_0}) - (\dim(V_\Psi) + \dim(W_{\Psi_0}) - \dim(V_\Psi \cap W_{\Psi_0})) = p_{\Psi_0} - d_{\Psi_0} - p_\Psi + d_\Psi$  and that the canonical mapping

$$\bigcap_{\Psi \in \Gamma} (V_\Psi + W_{\Psi_0})/W_{\Psi_0} \rightarrow \bigcap_{\Psi \in \Gamma} (V_\Psi + W)/W \quad (18)$$

is an isomorphism. Then,

$$\begin{aligned} \dim \left( \bigcap_{\Psi \in \Gamma} (V_\Psi + W)/W \right) &= \dim \left( \bigcap_{\Psi \in \Gamma} (V_\Psi + W_{\Psi_0})/W_{\Psi_0} \right) \\ &= \dim \left( \bigcap_{\Psi \in \Gamma} (V_\Psi + W_{\Psi_0}) \right) - \dim(W_{\Psi_0}) \\ &= p_{\Psi_0} - d_{\Psi_0} - \sum_{\Psi \in \Gamma} (p_{\Psi_0} - d_{\Psi_0} - p_\Psi + d_\Psi) \\ &= (1 - |\Gamma|)(p_{\Psi_0} - d_{\Psi_0}) + \sum_{\Psi \in \Gamma} (p_\Psi - d_\Psi). \end{aligned}$$

If the mapping is not onto, the second equality in this proof must be replaced by  $\leq$  and the next to last equality above must be replaced by  $\geq$ .

If  $|\Gamma| = 1$ , say  $\Gamma = \{\Psi\}$ , then (16) becomes  $V_\Psi \rightarrow V_\Psi/(V_\Psi + W_\Psi)$ , which is clearly onto. Suppose that  $|\Gamma| = 2$ , namely  $\Gamma = \{\Psi_1, \Psi_2\}$ . Let  $\tilde{v} = (\tilde{v}_2, \tilde{v}_1) \in V_{\Psi_0}/(V_{\Psi_1} + W_{\Psi_0}) \times V_{\Psi_0}/(V_{\Psi_2} + W_{\Psi_0})$ . Since  $V_{\Psi_0} = V_{\Psi_1} + V_{\Psi_2}$ , there is a  $v_2 \in V_{\Psi_2} \cap \tilde{v}_2$ , and similarly for  $v_1$ . Then,  $v = v_1 + v_2 \in V_{\Psi_0}$  is mapped to  $\tilde{v}$ . So, the mapping (16) is again onto. ■

Below, we give specific tables for the cases  $J = 2$  and  $J = 3$ . For  $J = 2$  all the  $c_\Phi$ 's can be computed easily from Theorem 3. For  $J = 3$ , Theorem 3 gives us one equation for each set  $\Gamma \in \Delta$ , except for one, for which the mapping (16) is not onto. We obtain this last equation and show how all the  $c_\Phi$ 's can be computed by considering a special lattice, different from the  $L_\Psi$ 's, and its successive minima. Below,  $\Phi$  denotes the signature of  $X$ .

## 5.2. Two simple components

For  $J = 2$ ,  $\text{card}(\Omega) = 5$  as shown in Table 2. We number these signatures from 1 to 5 and, to simplify the notation, we will replace each signature  $\Phi$  by its corresponding number when used as a subscript of  $c$ . In this case, Theorem 3 gives us an equation for each set  $\Gamma$ , as shown in Table 3.

Table 2: Possible signatures and frequencies for generators with two components.

$n$	$\Phi$	$f_l(X)$
1	$\{\{1, 2\}\}$	$2^d$
2	$\{\{1, 2\}, \{1\}\}$	$2^d - 2^{d_1}$
3	$\{\{1, 2\}, \{2\}\}$	$2^d - 2^{d_2}$
4	$\{\{1, 2\}, \{1\}, \{2\}\}$	$2^d - 2^{d_1} - 2^{d_2}$
5	$\{\{1, 2\}, \{1\}, \{2\}, \phi\}$	$2^d - 2^{d_1} - 2^{d_2} + 1$

Table 3: Equations given by Theorem 3, for  $J = 2$ .

$\Gamma$	equation
$\{\{1, 2\}\}$	$c_1 + c_2 + c_3 + c_4 + c_5 = 2^{p-d}$
$\{\{1\}\}$	$c_2 + c_4 + c_5 = 2^{p_1-d_1}$
$\{\{2\}\}$	$c_3 + c_4 + c_5 = 2^{p_2-d_2}$
$\{\{1\}, \{2\}\}$	$c_4 + c_5 = 2^{d-d_1-d_2}$
$\{\phi\}$	$c_5 = 1$

Solving the equations of Table 3, one obtains:

$$\begin{aligned}
c_5 &= 1, \\
c_4 &= 2^{d-d_1-d_2} - 1, \\
c_3 &= 2^{p_2-d_2} - 2^{d-d_1-d_2}, \\
c_2 &= 2^{p_1-d_1} - 2^{d-d_1-d_2}, \\
c_1 &= 2^{p-d} + 2^{d-d_1-d_2} - 2^{p_1-d_1} - 2^{p_2-d_2}.
\end{aligned}$$

These results are summarized in Table 4, where the first column gives all possible values of  $n$  for which  $\varphi_l(n)$  is not always zero. The integers  $d, d_1$  and  $d_2$  are obtained from Theorem 2 applied to  $L, L_1$ , and  $L_2$ , respectively, with  $r = -l$ . (Note that the fourth entry of the first column in Table 4 might be equal to  $-1$ , but that then the corresponding entry in the second column is zero.) To have the points “well distributed” among the cells, one would like to have first the smallest possible  $d$ , then the smallest  $d_1$  and  $d_2$ . The best case is  $d = p - lk$  and  $d_1 = d_2 = 0$ , which could occur only when  $lk \leq p$ .

Table 4: Values of  $\varphi_l(n)$  that could be non-zero, for  $J = 2$ .

$n$	$\varphi_l(n)$
$2^d$	$2^{p-d} + 2^{d-d_1-d_2} - 2^{p_1-d_1} - 2^{p_2-d_2}$
$2^d - 2^{d_1}$	$2^{p_1-d_1} - 2^{d-d_1-d_2}$
$2^d - 2^{d_2}$	$2^{p_2-d_2} - 2^{d-d_1-d_2}$
$2^d - 2^{d_1} - 2^{d_2}$	$2^{d-d_1-d_2} - 1$
$2^d - 2^{d_1} - 2^{d_2} + 1$	1
0	$2^{lk} - 2^{p-d}$

### 5.3. Three simple components

For  $J = 3$ ,  $\text{card}(\Omega) = 19$  as shown in Table 5. Again, we number these signatures from 1 to 19 and use these numbers as subscripts of  $c$ .

For all those minimal families  $\Gamma$  whose cardinality is 1 or 2, Theorem 3 yields  $C_\Gamma$  directly. For  $\Gamma = \{\{1, 2\}, \{1, 3\}, \{2, 3\}\}$ , it can be verified that the mapping (16) is onto, so that Theorem 3 applies. Indeed, let  $\tilde{v} = (\tilde{v}_3, \tilde{v}_2, \tilde{v}_1) \in (V/(V_{12} + W)) \times (V/(V_{13} + W)) \times (V/(V_{23} + W))$ . Since  $V = V_{12} + V_3$ , there is a  $v_3 \in V_3 \cap \tilde{v}_3$ , and similarly for  $v_2$  and  $v_1$ . Then,  $v = v_1 + v_2 + v_3 \in V$  is mapped to  $\tilde{v}$  by (16). There remains the case  $\Gamma = \{\{1\}, \{2\}, \{3\}\}$ , which is more difficult and is taken care of by Lemma 3 below. These results are summarized in Table 6. From the equations of Table 6, the  $c_i$ 's (i.e., the values of  $\varphi_l(n)$ ) can be computed easily.

We now explain how to deal with  $\Gamma = \{\{1\}, \{2\}, \{3\}\}$ , i.e. how to compute  $D = \dim(((V_1 + W) \cap (V_2 + W) \cap (V_3 + W))/W)$ . For this case, the mapping (16) is not onto in general and  $D$  cannot be determined by only the  $p_\Phi$ 's and  $d_\Phi$ 's. We give examples of that at the end of the appendix. Consider the lattice  $L' = L_{12} \times L_{13} \times L_{23} \subset K^{3k}$  and the mapping  $\eta : K^{3k} \mapsto K^k$  defined by  $\eta(v_1, v_2, v_3) = v_1 + v_2 + v_3$ . Let  $\bar{L} = L' \cap \ker(\eta) = \{v \in L' \mid \eta(v) = 0\}$ , the kernel of  $\eta$  restricted to  $L'$ . We then have:

**LEMMA 3.**  $D = \dim(\bar{L} \cap C_{-l}) - d_1 - d_2 - d_3$ .

**PROOF.** Let  $\bar{W} = W_{12} + W_{13} + W_{23}$  and  $\bar{d} = \dim(\bar{W})$ . From Lemma 6 in the appendix, one has

$$D = d_{12} + d_{13} + d_{23} - d_1 - d_2 - d_3 - \bar{d}. \quad (19)$$

Table 5: Possible signatures and frequencies for generators with three components.

$n$	$\Phi$	$f_l(X)$
1	$\{\{1, 2, 3\}\}$	$2^d$
2	$\{\{1, 2, 3\}, \{1, 2\}\}$	$2^d - 2^{d_{12}}$
3	$\{\{1, 2, 3\}, \{1, 3\}\}$	$2^d - 2^{d_{13}}$
4	$\{\{1, 2, 3\}, \{2, 3\}\}$	$2^d - 2^{d_{23}}$
5	$\{\{1, 2, 3\}, \{1, 2\}, \{1, 3\}\}$	$2^d - 2^{d_{12}} - 2^{d_{13}}$
6	$\{\{1, 2, 3\}, \{1, 2\}, \{2, 3\}\}$	$2^d - 2^{d_{12}} - 2^{d_{23}}$
7	$\{\{1, 2, 3\}, \{1, 3\}, \{2, 3\}\}$	$2^d - 2^{d_{13}} - 2^{d_{23}}$
8	$\{\{1, 2, 3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}\}$	$2^d - 2^{d_{12}} - 2^{d_{13}} - 2^{d_{23}}$
9	$\{\{1, 2, 3\}, \{1, 2\}, \{1, 3\}, \{1\}\}$	$2^d - 2^{d_{12}} - 2^{d_{13}} + 2^{d_1}$
10	$\{\{1, 2, 3\}, \{1, 2\}, \{2, 3\}, \{2\}\}$	$2^d - 2^{d_{12}} - 2^{d_{23}} + 2^{d_2}$
11	$\{\{1, 2, 3\}, \{1, 3\}, \{2, 3\}, \{3\}\}$	$2^d - 2^{d_{13}} - 2^{d_{23}} + 2^{d_3}$
12	$\{\{1, 2, 3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1\}\}$	$2^d - 2^{d_{12}} - 2^{d_{13}} - 2^{d_{23}} + 2^{d_1}$
13	$\{\{1, 2, 3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{2\}\}$	$2^d - 2^{d_{12}} - 2^{d_{13}} - 2^{d_{23}} + 2^{d_2}$
14	$\{\{1, 2, 3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{3\}\}$	$2^d - 2^{d_{12}} - 2^{d_{13}} - 2^{d_{23}} + 2^{d_3}$
15	$\{\{1, 2, 3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1\}, \{2\}\}$	$2^d - 2^{d_{12}} - 2^{d_{13}} - 2^{d_{23}} + 2^{d_1} + 2^{d_2}$
16	$\{\{1, 2, 3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1\}, \{3\}\}$	$2^d - 2^{d_{12}} - 2^{d_{13}} - 2^{d_{23}} + 2^{d_1} + 2^{d_3}$
17	$\{\{1, 2, 3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{2\}, \{3\}\}$	$2^d - 2^{d_{12}} - 2^{d_{13}} - 2^{d_{23}} + 2^{d_2} + 2^{d_3}$
18	$\{\{1, 2, 3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1\}, \{2\}, \{3\}\}$	$2^d - 2^{d_{12}} - 2^{d_{13}} - 2^{d_{23}} + 2^{d_1} + 2^{d_2} + 2^{d_3}$
19	$\{\{1, 2, 3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1\}, \{2\}, \{3\}, \phi\}$	$2^d - 2^{d_{12}} - 2^{d_{13}} - 2^{d_{23}} + 2^{d_1} + 2^{d_2} + 2^{d_3} - 1$

But since  $\eta(W_{12} \times W_{13} \times W_{23}) = \bar{W}$ , one has

$$\begin{aligned}
 \dim(\bar{L} \cap C_{-l}) &= \dim(\ker(\eta) \cap (W_{12} \times W_{13} \times W_{23})) \\
 &= \dim(W_{12} \times W_{13} \times W_{23}) - \dim(\bar{W}) \\
 &= d_{12} + d_{13} + d_{23} - \bar{d}.
 \end{aligned} \tag{20}$$

Merging (19) and (20) completes the proof. ■

We can now compute  $D$  using Theorem 2 by determining  $\bar{L}$ 's successive minima. For this, we must construct a basis for  $\bar{L}$ , which can then be reduced by Lenstra's algorithm [4].

We first find a set of vectors that generate  $\bar{L}$ . An element of  $L'$  can be written as  $v = (v_1 + v_2, v'_1 + v'_3, v''_2 + v''_3)$  with  $v_1, v'_1 \in L_1, v_2, v''_2 \in L_2$  and  $v'_3, v''_3 \in L_3$ . Such a  $v$  belongs to  $\bar{L}$  if and only if

$$v_1 + v'_1 + v_2 + v''_2 + v'_3 + v''_3 = 0. \tag{21}$$

We will now work in  $L$  modulo  $A^k$ , i.e. in the quotient group  $L/A^k$ . In that group,  $L$  is the direct sum of  $L_1, L_2$ , and  $L_3$ . This comes from (9) and noticing that the mapping "frac" induces a projection  $L \rightarrow L \cap C_0$  with kernel  $A^k$  (and the same for  $L_1, L_2$  and  $L_3$ ). So, we obtain from (21),  $v_1 + v'_1 = v_2 + v''_2 = v'_3 + v''_3 = 0$  modulo  $A^k$  and  $v$  can be written as  $(v_1 + v_2, -v_1 + v_3, -v_2 - v_3) = (v_1, -v_1, 0) + (v_2, 0, -v_2) + (0, v_3, -v_3)$  (each term  $\in \bar{L}$ ) plus something in  $A^{3k}$  which must also be in  $\bar{L}$ . So, a generating system for  $\bar{L}$  is obtained as the union of a basis for  $A^{3k} \cap \ker(\eta)$ ,  $\{(v_1, -v_1, 0)\}$ ,  $\{(v_2, 0, -v_2)\}$  and  $\{(0, v_3, -v_3)\}$ , where  $v_1, v_2$

Table 6: Equations given by Theorem 3 for  $J = 3$ .

$\Gamma$	equation
$\{\{1, 2, 3\}\}$	$c_1 + c_2 + \dots + c_{19} = 2^{p-d}$
$\{\{1, 2\}\}$	$c_2 + c_5 + c_6 + c_8 + c_9 + c_{10} + c_{12} + \dots + c_{19} = 2^{p_{12}-d_{12}}$
$\{\{1, 3\}\}$	$c_3 + c_5 + c_7 + c_8 + c_9 + c_{11} + c_{12} + \dots + c_{19} = 2^{p_{13}-d_{13}}$
$\{\{2, 3\}\}$	$c_4 + c_6 + c_7 + c_8 + c_{10} + c_{11} + c_{12} + \dots + c_{19} = 2^{p_{23}-d_{23}}$
$\{\{1, 2\}, \{1, 3\}\}$	$c_5 + c_8 + c_9 + c_{12} + \dots + c_{19} = 2^{p_1+d-d_{12}-d_{13}}$
$\{\{1, 2\}, \{2, 3\}\}$	$c_6 + c_8 + c_{10} + c_{12} + \dots + c_{19} = 2^{p_2+d-d_{12}-d_{23}}$
$\{\{1, 3\}, \{2, 3\}\}$	$c_7 + c_8 + c_{11} + c_{12} + \dots + c_{19} = 2^{p_3+d-d_{13}-d_{23}}$
$\{\{1, 2\}, \{1, 3\}, \{2, 3\}\}$	$c_8 + c_{12} + \dots + c_{19} = 2^{2d-d_{12}-d_{13}-d_{23}}$
$\{\{2, 3\}, \{1\}\}$	$c_{12} + c_{15} + c_{16} + c_{18} + c_{19} = 2^{d-d_1-d_{23}}$
$\{\{1, 3\}, \{2\}\}$	$c_{13} + c_{15} + c_{17} + c_{18} + c_{19} = 2^{d-d_2-d_{13}}$
$\{\{1, 2\}, \{3\}\}$	$c_{14} + c_{16} + c_{17} + c_{18} + c_{19} = 2^{d-d_3-d_{12}}$
$\{\{1\}\}$	$c_9 + c_{12} + c_{15} + c_{16} + c_{18} + c_{19} = 2^{p_1-d_1}$
$\{\{2\}\}$	$c_{10} + c_{13} + c_{15} + c_{17} + c_{18} + c_{19} = 2^{p_2-d_2}$
$\{\{3\}\}$	$c_{11} + c_{14} + c_{16} + c_{17} + c_{18} + c_{19} = 2^{p_3-d_3}$
$\{\{1\}, \{2\}\}$	$c_{15} + c_{18} + c_{19} = 2^{d_{12}-d_1-d_2}$
$\{\{1\}, \{3\}\}$	$c_{16} + c_{18} + c_{19} = 2^{d_{13}-d_1-d_3}$
$\{\{2\}, \{3\}\}$	$c_{17} + c_{18} + c_{19} = 2^{d_{23}-d_2-d_3}$
$\{\{1\}, \{2\}, \{3\}\}$	$c_{18} + c_{19} = 2^D$
$\{\emptyset\}$	$c_{19} = 1$

and  $v_3$  run through a basis of  $L_1, L_2$ , and  $L_3$ , respectively. Finally, a basis for  $A^{3k} \cap \ker(\eta)$  is given by  $\{e_i - e_{i+k}, e_i - e_{i+2k} \mid i = 1 \dots k\}$  where  $e_i \in A^{3k}$  is the vector with all components 0 with the exception of the  $i$ -th one which is the polynomial equal to 1.

It now remains to transform this generating system into a basis for  $\bar{L}$ . This is similar to the corresponding problem for lattices in  $\mathbb{R}^n$ , but now, integral linear combination means a linear combination with coefficients in  $A$ . So, let  $X_1, \dots, X_n$  denote a generating system, each vector having been multiplied by the modulus  $m$  so that all coordinates now belong to  $A$ . If some of these  $X_i$ 's have a non-zero first coordinate, one may construct, by the usual process of finding a gcd, a linear combination of them, say  $X$ , with the property that the first coordinate of  $X$  divides (in  $A$ ) the first coordinate of each  $X_i$ . One can then, by adding an integral multiple of  $X$  to the  $X_i$ 's, modify them so that their first coordinate is 0. We now have a new generating system formed by the modified  $X_i$ 's, together with  $X$ . In case all  $X_i$ 's had zero first coordinate from the start, we just do nothing at this step. Then, we repeat the process for the second coordinate of the  $X_i$ 's, etc., each time obtaining possibly a new  $X$ . At each step, the  $X_i$ 's, together with all the obtained  $X$ 's, still form a generating system for  $\bar{L}$ . Once the process is terminated for all coordinates, all the  $X_i$ 's are zero and we can forget them. The basis is then the set of  $X$ 's divided by the modulus  $m$ .

## 6. EXAMPLES

In this section, a LS2 (or Tausworthe) generator  $g$  with multiplier  $a$  and modulo  $m$  will be denoted by  $g = (a, m)$ , and our use of Theorem 2 will always be with  $h = k$  and  $r = -l$ .

### 6.1. A Combination of Two or Three Toy Generators

As a first illustration, we examine in detail the (low-dimensional) behavior of the three simple “toy” generators  $g_1 = (x, x^3 + x + 1)$ ,  $g_2 = (x^2, x^4 + x + 1)$ , and  $g_3 = (x^3, x^5 + x^2 + 1)$ , as well as the combination  $g_{23}$  of the last two, and the combination  $g_{123}$  of all three. Since  $\gcd(2^5 - 1, 2^4 - 1) = \gcd(31, 15) = 1$ , the period of  $g_{23}$  is  $31 \times 15 = 465$ . Similarly, since  $\gcd(2^3 - 1, 465) = 1$ , the period of  $g_{123}$  is  $465 \times 7 = 3255$ .

Table 7: Dimensions associated with  $g_1, g_2, g_3$ , and their combinations, for  $k = 2$ .

Table 7 gives all the kernel dimensions referred to in Tables 1–6, for  $k = 2$ . These have been computed using Theorem 2 and Lemma 3. From these values, we have computed the  $\varphi_l(n)$ 's for different values of  $l$ , for the generators  $g_1, g_2, g_3, g_{23}$ , and  $g_{123}$ . These are given in Tables 8 and 9. One can see that  $g_1, g_2$ , and  $g_3$  reach the best possible resolution considering

their period length, for all  $l$ . But their periods are very small. For the combination  $g_{23}$ , one has  $d = p - lk$  (and maximum resolution) only for  $l \leq 3$ . For  $l = 4$  and  $l = 5$ , there are empty cells and also cells that contain more than one point. Note that for  $l = 1$  and 2, the number of cells with  $2^d$  points turns out to be zero. That kind of situation happens quite frequently. For  $g_{123}$ ,  $d = p - lk$  holds for  $l$  up to 6. After that, any cell will contain either 0 or 1 point. Observe that the values of  $d$ ,  $d_i$ , or  $d_{ij}$  never increase when  $l$  increases. But this does not necessarily hold for  $D$ .

Table 10 gives the values that correspond to  $g_{23}$  in dimension  $k = 3$ . One has  $d = p - lk$  for  $l \geq 3$ . Despite that, for  $l = 3$ , there are 47 empty cells, due to the fact that in this case,  $n = 0$  for lines 2, 3, and 5 in Table 4.

Figure 1 shows all the points produced by the generator  $g_{23}$ , in dimension  $k = 2$ . This illustrates the results of the left-hand part of Table 9. For example, the grid on the figure partitions the square into  $2^6 = 64$  cells, which corresponds to  $l = 3$ . As indicated by Table 9, 24 cells contain 8 points, 33 cells contain 7 points, and 7 cells contain 6 points. If the grid was refined to partition the square into  $2^8 = 256$  cells (i.e.  $l = 4$ ), then, as indicated by Table 9, there would be 128 empty cells while the other cells would contain either 2, 3, or 4 points.

Figure 1: The pairs  $(u_i, u_{i+1})$ , produced by the combined Tausworthe generator  $g_{23}$ .

## 6.2. A Simple Generator From André, Mullen, and Niederreiter

We now examine a simple Tausworthe generator based on a polynomial of degree  $p = 32$ , which has been obtained by André et al. [1] and called “universally optimal”. This generator is  $g_A = (x^{32}, x^{32} + x^{31} + x^{30} + x^{28} + x^{27} + x^{26} + x^{24} + x^{22} + x^{21} + x^{12} + x^{11} + x^9 + x^8 + x^7 + x^6 + x^5 + x^4 + x^3 + x^2 + x + 1)$ . Table 11 gives the values of  $d$  for all dimensions  $k \leq 10$ , and all  $l$ . For  $l > 16$  and for the entries marked “-”, one has  $d = 0$ . There are only three non-zero entries for which  $d > p - lk$ , i.e., for which one does not have  $k$ -distribution with resolution  $l$ , and these are the three entries with  $d = 1$ . Table 12 shows what happens with the values of Table 1 for each of these three cases: there are  $2^{31}$  empty cells and  $2^{31} - 1$  cells that contain two points each.

Table 11: The values of  $d$  in dimensions  $k = 2$  to 10, for generator  $g_A$ .

	1	1
	0	$2^{31}$

### 6.3. A Simple Generator From Mullen and Niederreiter

Here, we look at another so-called “optimal polynomial”, suggested in Mullen and Niederreiter [9]. This one has degree 64 and yields the generator  $g_M = (x^{64}, x^{64} + x^{63} + x^{60} + x^{59} + x^{58} + x^{54} + x^{49} + x^{32} + 1)$ . Table 13 gives the values of  $d$  for all dimensions  $k \leq 5$ , and all  $l \geq 11$ . For  $k = 3$ , one has  $d > p - lk$  for all  $l \geq 17$ . Also,  $d > p - lk$  for  $k = 5$  and  $l = 13$ . Table 14 shows what happens with  $\varphi_l(n)$  in dimension  $k = 3$ . For example, with  $l = 21$ , one has approximately  $2^{63}$  empty cells and  $2^{53}$  cells that contain  $2^{11}$  points each. This is not very good.

Table 13: The values of  $d$  in dimensions of  $k = 2$  to 5, for generator  $g_M$ .

32	-	-	-	-

### 6.4. A Combined Tausworthe Generator Taken From SUPER-DUPER

Our last example is a combined Tausworthe generator, which is itself a component of the generator Super-Duper proposed by Marsaglia [8]. This generator is given by  $g = (x^{32}, x^{32} + x^{15} + 1)$ . Note that  $M(x) = x^{32} + x^{15} + 1$  is not irreducible and can be written as  $M(x) =$

Table 14: Values of  $\varphi_l(n)$  for  $g_M$  in dimension  $k = 3$ .

$k = 3$		
$l$	$n$	$\varphi_l(n)$
16	$2^{16}$	$2^{48} - 1$
	$2^{16} - 1$	1

12	8	0	0
13	6	0	0
14	4	0	0
15	2	0	0
16	1	0	0

$k = 3$			
$l$	$d$	$d_1$	$d_2$
1	29	18	8
2	26	15	5
3	24	13	3
4	22	11	1
5	20	9	0
6	18	7	0
7	16	5	0
8	14	3	0
9	12	1	0
10	10	0	0

$k = 4$			
$l$	$d$	$d_1$	$d_2$
1	28	17	7
2	24	13	3
3	22	11	1
4	20	9	0
5	18	7	0
6	16	5	0
7	14	3	0
8	12	1	0
9	10	0	0
10	8	0	0

$(x^{21} + x^{19} + x^{15} + x^{13} + x^{12} + x^{10} + x^9 + x^8 + x^7 + x^6 + x^4 + x^2 + 1)(x^{11} + x^9 + x^7 + x^2 + 1)$ . So, this generator can be regarded as a combined Tausworthe generator. The maximum possible period is  $(2^{21} - 1)(2^{11} - 1)$  and thereby almost all initial values give the maximum period. Table 15 gives the values of  $d$ ,  $d_1$ , and  $d_2$  for all  $l$ , in dimensions 2 to 4. From that, one can use Table 4 to compute  $\varphi_l(n)$ . The results are given in Table 16. Here, the values for which maximum resolution ( $d = p - lk$ ) is not attained are  $l = 16$  for  $k = 2$ , and all  $l \geq 3$  for  $k = 3$  and 4. Therefore, bad behavior is to be expected in dimensions 3 and 4. Table 16 confirms that. For example, in dimension 3 and with  $l = 6$ , there are 245760 empty cells, 2047 cells that contain 262015 points each, and 14337 cells that contain 262016 points each.

## APPENDIX

In this appendix, we derive a technical result that was used in the proof of Lemma 3 in Section 5.3. Let  $V = V_1 + V_2 + V_3$  be a direct sum of vector spaces and  $W \subset V$  a subspace. For each  $i \neq j$ , let  $W_i = W \cap V_i$ ,  $W_{ij} = W \cap (V_i + V_j)$ ,  $d = \dim(W)$ ,  $d_i = \dim(W_i)$ , and  $d_{ij} = \dim(W_{ij})$ . Let

$$\bar{W} = W_{12} + W_{13} + W_{23} \quad (22)$$

and  $\bar{d} = \dim(\bar{W})$ . Let  $D = \dim(((V_1 + W) \cap (V_2 + W) \cap (V_3 + W))/W)$ . Our aim is now to express  $D$  as a function of quantities defined above.

Let  $W_0 = W_1 + W_2 + W_3$  and for each subspace  $E$  of  $V$ , let  $\tilde{E}$  denote the image of  $E$  by the canonical mapping  $V \rightarrow V/W_0$ . We will perform a reduction of everything modulo  $W_0$ . The development will then be easier in space  $\tilde{V}$  due to the fact that  $\tilde{W} \cap \tilde{V}_i = \tilde{W}_i = \{0\}$  for each  $i$ . For each  $i$  and  $j \neq i$ , one has the following:

$$\begin{aligned} \tilde{V} &= \tilde{V}_1 + \tilde{V}_2 + \tilde{V}_3 \quad (\text{direct sum}); \\ \tilde{W}_i &= \tilde{W} \cap \tilde{V}_i = \{0\}; \\ \tilde{W}_{ij} &= \tilde{W} \cap (\tilde{V}_i + \tilde{V}_j); \\ \tilde{d}_{ij} &\stackrel{\text{def}}{=} \dim(\tilde{W}_{ij}) = \dim(\tilde{W} \cap (\tilde{V}_i + \tilde{V}_j)) = \dim(W_{ij}) - \dim(W_{ij} \cap W_0) \\ &= \dim(W_{ij}) - \dim(W_i + W_j) = d_{ij} - d_i - d_j; \\ \tilde{d} &\stackrel{\text{def}}{=} \dim(\tilde{W}) = \dim(W) - \dim(W_0) = d - d_1 - d_2 - d_3. \end{aligned} \quad (23)$$

One has  $\tilde{W} \stackrel{\text{def}}{=} \sum_{i \neq j} \tilde{W}_{ij} = \tilde{W}$  and

$$\tilde{d} \stackrel{\text{def}}{=} \dim(\tilde{W}) = \bar{d} - d_1 - d_2 - d_3. \quad (24)$$

Finally,

$$\dim((V_1 + W) \cap (V_2 + W) \cap (V_3 + W)) = \dim((\tilde{V}_1 + \tilde{W}) \cap (\tilde{V}_2 + \tilde{W}) \cap (\tilde{V}_3 + \tilde{W})) + d_1 + d_2 + d_3. \quad (25)$$

Let  $H_1 = \tilde{V}_1 \cap (\tilde{V}_2 + \tilde{W}_{12}) \cap (\tilde{V}_3 + \tilde{W}_{13})$ .

**LEMMA 4.** *One has*

$$(\tilde{V}_1 + \tilde{W}) \cap (\tilde{V}_2 + \tilde{W}) \cap (\tilde{V}_3 + \tilde{W}) = H_1 + \tilde{W} \quad (26)$$

and  $D = \dim(H_1)$ .

**PROOF.** Let  $v_1 + w_1 = v_2 + w_2 = v_3 + w_3$  be a common element to the three spaces that intersect on the left in equation (26). One then has  $v_1 = v_2 + (w_2 - w_1) = v_3 + (w_3 - w_1)$ , where  $w_2 - w_1 \in \tilde{W}_{12}$  and  $w_3 - w_1 \in \tilde{W}_{13}$ . Therefore,  $v_1$  belongs to  $H_1$  and the set on the left is a subset of the one on the right. The inclusion in the other direction is immediate.

Since  $H_1 \subseteq \tilde{V}_1$ ,  $H_1 \cap \tilde{W}$  is a subset of  $\tilde{W}_1$  and is therefore  $\{0\}$ . This means that the sum  $H_1 + \tilde{W}$  is direct. Then, from (26) and (25), one has

$$\begin{aligned} D &= \dim((\tilde{V}_1 + \tilde{W}) \cap (\tilde{V}_2 + \tilde{W}) \cap (\tilde{V}_3 + \tilde{W})) + d_1 + d_2 + d_3 - d \\ &= \dim(H_1) + \dim(\tilde{W}) + d_1 + d_2 + d_3 - d \\ &= \dim(H_1). \blacksquare \end{aligned}$$

Let  $\pi_i$  denote the canonical projection  $\tilde{V} \mapsto \tilde{V}_i$ . Since  $\tilde{W}_i = \{0\}$ , for each  $v_1 \in H_1$  there are unique elements  $w_{12} \in \tilde{W}_{12}$  and  $w_{13} \in \tilde{W}_{13}$  such that  $\pi_1(w_{12}) = \pi_1(w_{13}) = v_1$ . We can then define a linear mapping  $\mu : H_1 \mapsto \tilde{W}_{23}$  by  $\mu(v_1) = \pi_2(w_{12}) - \pi_3(w_{13}) (= w_{12} - w_{13}, \text{ since } \pi_1(w_{12} - w_{13}) = 0)$ .

**LEMMA 5.** *The mapping  $\mu$  is one-to-one and  $\mu(H_1) = (\tilde{W}_{12} + \tilde{W}_{13}) \cap \tilde{W}_{23}$ .*

PROOF. If  $\mu(v_1) = 0$ , then  $w_{12} = w_{13} \in (\tilde{V}_1 + \tilde{V}_2) \cap (\tilde{V}_1 + \tilde{V}_3) = \tilde{V}_1$  so that  $w_{12} = w_{13} = 0$  and  $v_1 = \pi_1(w_{12}) = 0$ . This implies that  $\mu$  is one-to-one. By construction, we have  $\mu(H_1) \subset (\tilde{W}_{12} + \tilde{W}_{13}) \cap \tilde{W}_{23}$  and it remains to show the reverse inclusion. Let  $w_{23} = w_{12} - w_{13} \in (\tilde{W}_{12} + \tilde{W}_{13}) \cap \tilde{W}_{23}$  and  $v = \pi_1(w_{12})$ . Since  $\pi_1(w_{23}) = 0$ , we have  $\pi_1(w_{13}) = \pi_1(w_{12}) = v$  and  $v \in H_1$ . Then, from the definition of  $\mu$ ,  $\mu(v) = w_{23}$  and this completes the proof.  $\blacksquare$

**LEMMA 6.**

$$\begin{aligned} D = \dim(H_1) &= \tilde{d}_{12} + \tilde{d}_{13} + \tilde{d}_{23} - \dim(\tilde{W}) \\ &= d_{12} + d_{13} + d_{23} - d_1 - d_2 - d_3 - \bar{d}. \end{aligned} \quad (27)$$

PROOF. Keeping in mind that the sum  $\tilde{W}_{12} + \tilde{W}_{13}$  is direct because each  $\tilde{W}_i$  is  $\{0\}$ , and using the previous lemma, one has

$$\begin{aligned} \dim(\tilde{W}) &= \dim(\tilde{W}_{12} + \tilde{W}_{13} + \tilde{W}_{23}) \\ &= \dim(\tilde{W}_{23}) + \dim(\tilde{W}_{12} + \tilde{W}_{13}) - \dim((\tilde{W}_{12} + \tilde{W}_{13}) \cap \tilde{W}_{23}) \\ &= \tilde{d}_{23} + \tilde{d}_{12} + \tilde{d}_{13} - \dim(H_1). \end{aligned}$$

This gives the middle equality. The first equality is already contained in Lemma 4, while the last one follows from (23) and (24).  $\blacksquare$

The following example shows that knowing  $d$ , the  $d_i$ 's, and  $d_{ij}$ 's is not sufficient in general to compute  $D$ .

**EXAMPLE.** For  $i = 1, 2, 3$ , let  $\dim(V_i) = 2$  and let  $\{v_i, v'_i\}$  be a basis for  $V_i$ . We consider two cases. In the first case, suppose that  $W = \mathbb{F}_2 \cdot (v_1 + v'_2) + \mathbb{F}_2 \cdot (v_2 + v'_3) + \mathbb{F}_2 \cdot (v_3 + v'_1)$ , where  $\mathbb{F}_2 \cdot v$  means the space  $\{0, v\}$ . Then,  $W_i = W \cap V_i = \{0\}$  for each  $i$  and  $H_1 = V_1 \cap (V_2 + W_{12}) \cap (V_3 + W_{13}) = V_1 \cap (V_2 + \mathbb{F}_2 \cdot (v_1 + v'_2)) \cap (V_3 + \mathbb{F}_2 \cdot (v_3 + v'_1)) = V_1 \cap (V_2 + \mathbb{F}_2 \cdot v_1) \cap (V_3 + \mathbb{F}_2 \cdot v'_1) = (\mathbb{F}_2 \cdot v_1) \cap (\mathbb{F}_2 \cdot v'_1) = \{0\}$ , so that  $D = \dim(H_1) = 0$ . In the second case, suppose that  $W = \mathbb{F}_2 \cdot (v_1 + v_2) + \mathbb{F}_2 \cdot (v_1 + v_3) + \mathbb{F}_2 \cdot (v'_2 + v'_3)$ . Then,  $W \cap V_i = \{0\}$  for each  $i$  and  $H_1 = V_1 \cap (V_2 + W_{12}) \cap (V_3 + W_{13}) = V_1 \cap (V_2 + \mathbb{F}_2 \cdot (v_1 + v_2)) \cap (V_3 + \mathbb{F}_2 \cdot (v_1 + v_3)) = V_1 \cap (V_2 + \mathbb{F}_2 \cdot v_1) \cap (V_3 + \mathbb{F}_2 \cdot v_1) = \mathbb{F}_2 v_1$ , so that  $D = \dim(H_1) = 1$ . In both cases,  $d = 3$ ,  $d_{ij} = 1$ , and  $d_i = 0$ , but the two cases have different values of  $D$ .
