Overview

Two recent algorithms for reconstruction will be presented.

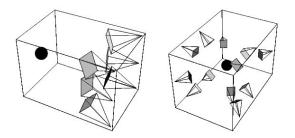

- Passive reconstruction
 - Multi-view stereo algorithm
 - Occlusion modeling
- ② Active reconstruction
 - Camera-projector system
 - Structured light reconstruction
 - Large multi-projector immersive projection

3D Reconstruction

Goal: Establish correspondance between two or more views of a scene to reconstruct by triangulation.

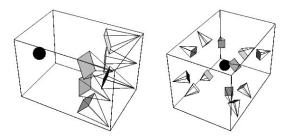

Stereo reconstruction

All cameras are on one "side" of the scene

- Only allows a partial reconstruction, from the point of view of a camera
- Pixel representation is typical (depth maps)

3D Reconstruction

Goal: Establish correspondance between two or more views of a scene to reconstruct by triangulation.

Volumetric reconstruction

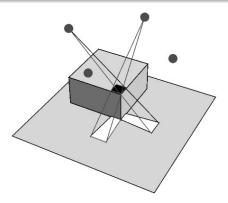

Cameras can "go around" the scene

- Allows a full reconstruction
- Voxel representation is typical

Occlusion

A point in the scene wich is not directly visible from a camera is *occluded*.

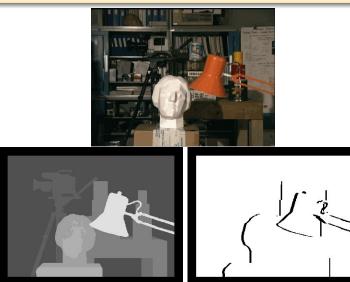

Occluded points affect correspondence as they are harder (or impossible) to match.

Camera separation increase precision, but also occlusion.

Stereo energy formulation

Occlusion depends on the camera configuration and on the depth variation in the scene.

Depth configuration

For a set of reference pixels $\mathcal P$ and a set of depth labels $\mathcal Z,$ a depth configuration f is

$$f: \mathcal{P} \mapsto \mathcal{Z}$$

The energy function to minimize is

$$E(f) = \sum_{\mathbf{p} \in \mathcal{P}} e(\mathbf{p}, f(\mathbf{p})) + \sum_{\mathbf{p} \in \mathcal{P}} \sum_{\mathbf{r} \in \mathcal{N}_{\mathbf{p}}} s(\mathbf{p}, \mathbf{r}, f(\mathbf{p}), f(\mathbf{r}))$$

- 日本 本語 本 本 田 本 本 田 本

500

 $\mathcal{N}_{\mathbf{p}}$ is the neighborhood of pixel $\mathbf{p}.$

Can be solved efficiently...

... since $e(\mathbf{p}, f(\mathbf{p}))$ is independent over \mathbf{p} .

Depth configuration

For a set of reference pixels ${\mathcal P}$ and a set of depth labels ${\mathcal Z},$ a depth configuration f is

$$f: \mathcal{P} \mapsto \mathcal{Z}$$

The energy function to minimize is

$$E(f) = \sum_{\mathbf{p} \in \mathcal{P}} e(\mathbf{p}, f(\mathbf{p})) + \sum_{\mathbf{p} \in \mathcal{P}} \sum_{\mathbf{r} \in \mathcal{N}_{\mathbf{p}}} s(\mathbf{p}, \mathbf{r}, f(\mathbf{p}), f(\mathbf{r}))$$

(日) (日) (日) (日) (日) (日) (日) (日)

 $\mathcal{N}_{\mathbf{p}}$ is the neighborhood of pixel $\mathbf{p}.$

Can be solved efficiently...

... since the smoothing term has a simple 2-clique form.

Visibility Masks

Volumetric visibility

Given a depth configuration f, the visibility of a 3D reference point ${\bf q}$ for camera i is

 $V_i(\mathbf{q}, f)$

(1 if visible, 0 if not)

Visibility mask

The visibility of point \mathbf{q} for N supporting cameras is a vector

$$\mathbf{V}(\mathbf{q},f) = \bigoplus_{i=1...N} V_i(\mathbf{q},f)$$

(q is always visible in the reference camera)

Visibility is a long-range interaction. Immediate neighbors are insufficient to compute it.

Visibility

Visibility configuration

For a set of possible visibility masks $\mathcal{M},$ a visibility configuration g is

 $g:\mathcal{P}\mapsto\mathcal{M}$

New energy visibility aware function is

$$E(f,g) = \sum_{\mathbf{p} \in \mathcal{P}} e(\mathbf{p}, f(\mathbf{p}), g(\mathbf{p})) + \mathsf{smoothing}$$

A typical matching term is

$$e(\mathbf{p}, z, \mathbf{m}) = rac{\mathbf{m} \cdot C(\mathbf{p}|z)}{|\mathbf{m}|}$$
 instead of $e(\mathbf{p}, z) = C(\mathbf{p}|z)$

- 3D points $\mathbf{p}|z$ is \mathbf{p} augmented by depth z
- $C(\mathbf{q})$ is a vector of matching costs for each camera
- $\bullet\,$ the l_1 norm $|\mathbf{m}|$ is the number of visible cameras
- the case $|\mathbf{m}| = 0$ is interesting...

Depth and Visibility

Let's try to disentangle visibility and depth...

Geo-consistency

A depth configuration f is geo-consistent with a visibility configuration g if

 $g(\mathbf{p}) \leq \mathbf{V}(\mathbf{p}|f(\mathbf{p}), f)$

for each components and all $\mathbf{p} \in \mathcal{P}$.

Intuitively

A geo-consistent depth configuration is still geo-consistent when removing too many cameras from the visibility.

A new problem

Solve E in depth f and visibility g, with the constraint that f is geo-consistent with g.

 $g(\mathbf{p}) \leq \mathbf{V}(\mathbf{p}|f(\mathbf{p}), f)$

for each components and all $\mathbf{p} \in \mathcal{P}$.

Intuitively

A geo-consistent depth configuration is still geo-consistent when removing too many cameras from the visibility.

A new problem

Solve E in depth f and visibility g, with the constraint that f is geo-consistent with g.

Some approaches...

All cameras visible

Set $g^0(\mathbf{p}) = (1, 1, ..., 1)$ for all \mathbf{p} . Solve $E(f, g^0)$. This is equivalent to solving only E(f).

Simultaneous depth and visibility

Test all combinations in $\mathcal{Z} \times \mathcal{M}$. This is an intractable search space

Reduce the set \mathcal{M}

For a given camera configuration, not all masks are possible. Still, the set is too big, or wrong.

Photo-consistency

Some approaches...

All cameras visible

Set $g^0(\mathbf{p}) = (1, 1, ..., 1)$ for all \mathbf{p} . Solve $E(f, g^0)$. This is equivalent to solving only E(f).

Simultaneous depth and visibility

Photo-consistency

A new implicit occlusion model

Make the dependency temporal

Let f^0 be the depth configuration minimizing $E(f, g^0)$. For t > 0, we minimize

$$\sum_{\mathbf{p}\in\mathcal{P}} e(\mathbf{p},f^t(\mathbf{p}),\mathbf{V}(\mathbf{p}|f^t(\mathbf{p}),f^{t-1})+\mathsf{smoothing}$$

where

$$g^t(\mathbf{p}) = \mathbf{V}(\mathbf{p}|f^t(\mathbf{p}), f^{t-1})$$

Intuitively

- Start solving depth with all cameras visible.
- Our set the current depth configuration to compute new visibility.
- Solve for depth using the new visibility, and go back to step 2.

A new implicit occlusion model

Make the dependency temporal

Let f^0 be the depth configuration minimizing $E(f, g^0)$. For t > 0, we minimize

$$\sum_{\mathbf{p}\in\mathcal{P}}e(\mathbf{p},f^t(\mathbf{p}),\mathbf{V}(\mathbf{p}|f^t(\mathbf{p}),f^{t-1})+\mathsf{smoothing}$$

where

$$g^t(\mathbf{p}) = \mathbf{V}(\mathbf{p}|f^t(\mathbf{p}), f^{t-1})$$

Intuitively

- Start solving depth with all cameras visible.
- ② Use the current depth configuration to compute new visibility.
- Solve for depth using the new visibility, and go back to step 2.

It's all nice, but...

Does it converge?

History of visibility

The new visibility mask is multiplied by the previous visibility. This ensures that once a camera is removed, it is never used again. This also ensures convergence.

Pseudo-visibility

- The depth of occluded pixels tends to be underestimated.
- These misplaced pixels can wrongly occlude other pixel.
- This makes closer objects appear larger.

Pseudo-visibility

Empirical study of misclassification of pixels.

bnv [2]	1.0	2.0	96.9	0.5	1.5	98.0

Pseudo-visibility

An occluder should be considered invisible, just like an occluded pixel.

The cost function is the same for all algorithms. The smoothing term is

$$s(\mathbf{p}, \mathbf{r}, f(\mathbf{p}), f(\mathbf{r})) = \lambda g(\mathbf{p}, \mathbf{r}) l(f(\mathbf{p}, f(\mathbf{r})))$$

where

$$g(\mathbf{p}, \mathbf{r}) = \left\{egin{array}{cc} 3 & ext{if } |I_{ref}(\mathbf{p}) - I_{ref}(\mathbf{q})| < 5 \ 1 & ext{otherwise} \end{array}
ight.$$

There is a lot to do to make the matching and smoothing cost more general.

Results

The algorithms are labelled as C-M where C is the cost function and M is the minimization algorithm used.

From Passive to Active

Passive reconstruction has a lot of problems to address

- photometric ambiguity
- visibility problem (geo-consistency)

To simplify the matching process, we can use a projector.

- Control the texture of scene objects
- Project codes to simplify correspondence

99% of industrial scanners use some form of active reconstruction

(日) (日) (日) (日) (日) (日) (日) (日)

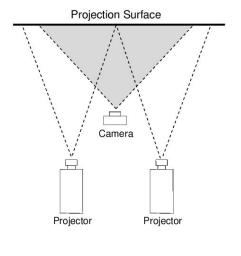

Projecting on anything

The future of projection is simple: project on any surface you wish, and cover that surface with many projectors.

Ideal case

- perfectly aligned projectors
- no radial distortion
- flat projection surface

Most common distortion: perspective solved by keystone adjustment

Structured Light patterns

For each projector pixel (x, y) we define a code $P(x, y) = x \oplus y$ (10+10 bits). A succession of pattern images P_i and their inverse \overline{P}_i is projected.

 $P_i(x,y) = \mathbf{bit}_i(P(x,y))$ and $\overline{P}_i(x,y) = 1 - P_i(x,y)$

Gray Codes

$$G(x) = x \quad \text{xor} \quad (x >> 1)$$

For to neighbor pixels x and x + 1, the number of changed bits is the number of black-white transitions in the pattern images.

x	0	1	2	3	4	5	6	7
P_0	0	1	0	1	0	1	0	1
P_1	0	0	1	1	0	0	1	1
P_2	0	0	0	0	1	1	1	1

Gray code ensure that one bit changes between consecutive codes.

G(x)	0	1	3	2	6	7	5	4
P_0	0	1	1	0	0	1	1	0
P_1	0	0	1	1	1	1	0	0
P_2	0	0	0	0	1	1	1	1

The camera record pattern P_i as image C_i , and \overline{P}_i as \overline{C}_i . To recover the code C(x, y)

$$C(x,y) = \bigoplus_i \operatorname{thresh}(C_i(x,y) - \overline{C}_i(x,y))$$

where

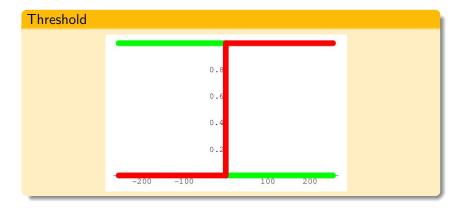

$$\mathbf{thresh}(v) = \left\{ egin{array}{cc} 1 & \mathrm{if}\,v > 0 \\ 0 & \mathrm{otherwise} \end{array}
ight.$$

Sites

Pixels (x, y) of the camera image.

Labels

All codes C(c, y) with non zero probability. (Codes are real, not Gray)

Smoothness term

Codes of neighboring pixels should be similar. (Absolute difference of codes)

Markov Random Fields

Sites

Pixels (x, y) of the camera image.

Labels

All codes C(c, y) with non zero probability. (Codes are real, not Gray)

Smoothness term

Codes of neighboring pixels should be similar. (Absolute difference of codes)

Solved using Maximum-flow, ICM, \dots (pick your favorite, the labels are 1-D ordered, the problem is easy to solve)

Example

- Two projectors setup
- Flat projection surface.
- Perspective camera

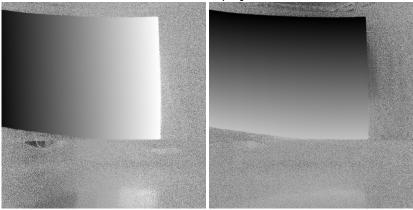

What the camera sees (with two projectors on):

3

Example corespondances

Camera to first projector...

 $\mathsf{Camera} \to \mathsf{Projector} \; \mathsf{X}$

 $\mathsf{Camera} \to \mathsf{Projector} \; \mathsf{Y}$

ヘロト 人間ト 人注ト 人注ト

Example corespondances

Camera to second projector...

 $\mathsf{Camera} \to \mathsf{Projector} \; \mathsf{X}$

 $\mathsf{Camera} \to \mathsf{Projector} \; \mathsf{Y}$

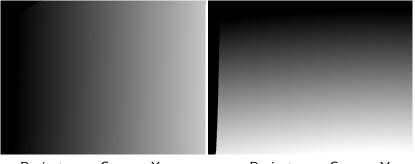

ヘロト ヘ回ト ヘヨト ヘヨト

Sac

Example inverse correspondences

The Camera-Projector correspondences must be inverted (carefully).

First projector to Camera...

 $\mathsf{Projector} \to \mathsf{Camera} \; \mathsf{X}$

 $\mathsf{Projector} \to \mathsf{Camera} \; \mathsf{Y}$

Example inverse correspondences

The Camera-Projector correspondences must be inverted (carefully).

 $\mathsf{Projector} \to \mathsf{Camera} \ \mathsf{X}$

 $\mathsf{Projector} \to \mathsf{Camera} \; \mathsf{Y}$

Conclusion

Reconstruction

- Occlusion is becoming the dominant problem in stereo
- Visibility maps are as important as depth itself
- N-camera stereo (N > 2) is a tremendous help
- Occlusion can be modelled on top of regular stereo algorithms

- Better occlusion benchmarks are needed
- ...

Immersion

- Immersion = multiple projectors and bad pixel ratios
- Accurate 3D reconstruction is possible.
- ...

A new camera model for distortion, in between: Bonjour, cet été un être.
